1 Week 12 Assignment

1.1 Problem 1

In the cell below, write a function that prints your name 5 times whenever it is called.

```
[1]: # creating the function
def print_nameA():
    for _ in range(5):
        print("Evelyn Barrera Castro")

# Calling the designed function
print_nameA()
```

Evelyn Barrera Castro
Evelyn Barrera Castro
Evelyn Barrera Castro
Evelyn Barrera Castro
Evelyn Barrera Castro

1.2 Problem 2

In the cell below, create a function that takes as input a length measurement in inches and returns the corresponding value in feet. Use your function to determine the number of feet that corresponds to 72 inches.

```
[2]: # define the function created
def convert_length(input_inches):
    # perform the logic conversion
    converted_length = input_inches / 12 # this is the fact that 12 inches
    ↪ equals 1 foot
    return converted_length

# converting 72 inches into feet
result = convert_length(72)
print(result) # printing result
```

6.0

1.3 Problem 3

In the cell below, create a function that takes a list as input and changes the third element of the given list to the number 3.

```
[3]: # creating a function that will modify the 3rd element
def change_3rd_element(input_list):
    # first check if the list has at least 3 elements
    if len(input_list) >= 3:
        input_list[2] = 3 # updates the 3rd element (indexed at 2)
    else:
        print ("Error: The given list does not have a 3rd element. Try Again.")

# Time to create the list
My_List = [1,2,15,4,5]

# Calling the function to do it's thing
change_3rd_element(My_List)
print(My_List)
```

```
[1, 2, 3, 4, 5]
```

1.4 Problem 4

In the cell below, create a function that takes as input a string `to_print` and an integer `repetitions` and prints the string `repetitions` times on separate lines.

```
[4]: # creating the function
def print_multiple_times (to_print, repetitions):
    for _ in range(repetitions): # defining repetitions as the range
        print(to_print) # calling to print the given string

# testing our function
print_multiple_times("Hello World!", 5)
```

```
Hello World!
Hello World!
Hello World!
Hello World!
Hello World!
```

1.5 Problem 5

In the cell below, create a function that simulates rolling a die and prints “You win!” if the roll is greater than 4, “You lose!” if the roll is less than 4, and re-rolls if the die is exactly 4.

```
[5]: # import needed for random
import random
```

```
# simulates die rolling
def rooll_die_game():
    while True: # Loop that will reroll
        die_roll = random.randint(1, 6)
        print(f"Rolled: {die_roll}")

        if die_roll > 4 and die_roll != 4:
            print ("You Win!")
            break # Exit the loop
        elif die_roll < 4:
            print ("You lose!")
            break # Again exit the loop
        elif die_roll == 4:
            print ("Re-rolling...")

# Calling the function
rooll_die_game()
```

Rolled: 2

You lose!

[]:
